SELECTED WORK / SYSTEMS & ANALYTICS

Operational Data Integration

How I cleaned up Salesforce and website data, then connected the records used for leads, course registrations, and product sales.

CLEAN THE DATA	CAPTURE & ROUTE	CONNECT SYSTEMS	TRACK CLIENT WORK

THE PROBLEM

The records did not agree.

The website, CRM, registration system, and online store were all in use, but information changed shape as it moved between them. Form answers could arrive in Salesforce in the wrong format. Prices could be mixed up. A completed registration could be hard to connect to the right person or company.

FIRST, THE CLEANUP

I fixed the fields before adding more automation.

I traced the fields and record relationships, checked what each system needed, and corrected the mappings. The main fixes fell into four areas:

Website forms	Converted multi-select answers to Salesforce picklist values and kept the reason for contact.
Record links	Kept Accounts, Contacts, courses, registrants, host sites, and locations distinct where needed.
Product data	Separated standard and member prices, with categories, dimensions, weight, and virtual status.
Campaign sources	Captured source, medium, and campaign details at the form, before that context was lost.

At that point I could start trusting what arrived at the next system. Otherwise I would only have automated the mistakes.

THE BUILD

What happened next

Once the records were consistent, I connected intake, follow-up, product updates, and customer history.

01 / LEADS

Get the right request to the right person

Website inquiries became Salesforce Leads with contact reason and campaign details. A record-triggered Flow chose an owner, notified staff, and created a follow-up Task.

02 / COMMERCE

Keep the store aligned with Salesforce

Zapier resolved products and separate price-book entries. A custom WordPress REST endpoint matched the product in WooCommerce, applied categories and prices, and kept shipping fields in sync.

03 / REGISTRATIONS

Keep student and course links intact

I worked through the relationships between Accounts, Contacts, courses, registrants, and purchases so participation could be viewed by person, company, or course.

04 / CONSULTING

Track the work after the first call

In Salesforce sandbox, I added an Account-based consultation model with engagement records, multiple contacts, and follow-up Tasks. Renewal alerts were proposed, not deployed.

What this gave the team

Leads arrived with more useful context for a first conversation. Product updates had a consistent path to the storefront. Registrations kept clearer links to people and companies. The consulting model gave staff a place to continue tracking a relationship after the initial inquiry.

These were improvements to day-to-day operations, not evidence of measured revenue growth. The consultation extension was built in sandbox.

What I would do sooner: agree on a field dictionary and stable matching keys before building the first integration. I spent extra time untangling those decisions later.

Public version: organization names, employee information, URLs, credentials, record IDs, and internal values have been removed or generalized.
