SELECTED WORK / SYSTEMS & ANALYTICS

Operational Data Integration

How I cleaned up records across a CRM, website, registration system, and online store — then made those records useful for automation and client follow-up.

CLEAN THE DATA	CAPTURE & ROUTE	CONNECT SYSTEMS	TRACK THE WORK

THE PROBLEM

A lot of the information already existed. It just didn’t line up.

Website leads, Salesforce records, course registrations, and WooCommerce orders were all doing their own jobs. But I kept finding gaps when information moved from one place to another: different field formats, unclear record matching, and details that were lost before anyone needed to report on them. A successful automation run could still leave behind bad data.

THE CLEANUP

I started with the field definitions, not the automation.

I traced how Accounts, Contacts, courses, participants, products, and purchases related to one another. Then I corrected form-to-CRM mappings, normalized multi-select values, separated standard and member pricing, and made record matching less dependent on display names.

Website fields	Translated checkbox selections to the CRM’s multi-select format so responses stayed distinct and reportable.
Record relationships	Kept person, employer, course, registrant, and location/host-site information separate where they meant different things.
Product data	Identified separate price-book entries and preserved categories, sizes, weight, and virtual-product status.
Marketing context	Captured source, medium, campaign, and the reason for contact before those details disappeared.

That groundwork made the later workflows reliable. Otherwise I would have been automating the same inconsistencies faster.

THE IMPLEMENTATION

Connecting the handoffs.

Once the incoming records were usable, I could focus on what happened next: who owned the inquiry, how the catalog stayed aligned, and how the customer relationship continued.

01 / LEADS

A clear first response

Website inquiries became Salesforce Leads with intent and UTM context. A record-triggered Flow assigned an owner, sent relevant staff notifications, and created a follow-up Task.

02 / COMMERCE

One product, consistent prices

Zapier separated related price-book rows and sent product data to a custom WordPress REST endpoint. The endpoint handled WooCommerce matching, create/update logic, pricing, categories, and fulfillment fields.

03 / REGISTRATIONS

Keep the relationships

Course records, attendees, Accounts, Contacts, and related purchases needed to stay connected. I worked through those relationships so participation could be understood beyond a single submission.

04 / CONSULTING

After the first inquiry

Consulting leads exposed a need for ongoing client history. In Salesforce sandbox I built an Account-centered engagement model with multiple contacts, engagement records, and follow-up Tasks.

WHY THIS WAS WORTH DOING

It became easier to use the data, not just collect it.

Staff had a better starting point for follow-up because intent and source information came with the Lead. Product data could be checked for missing prices and shipping details before reaching the storefront. Course and participant relationships became more useful for understanding demand and customer history. And consulting records could hold a longer relationship than the original Lead.

These were operational improvements and a foundation for attribution and BI, not a claim of measured revenue growth. The consultation model was implemented in sandbox; renewal alerts were a proposed next step.

> **What I would do earlier:** write the field dictionary and choose stable matching keys before building an integration. It saves rework later.

Sanitized for public use: organization names, individuals, URLs, credentials, record IDs, and internal configuration values have been removed or generalized.
