Operational Data Integration

Rebuilding the data and workflows behind customer inquiries, training operations, and ecommerce.

DATA FOUNDATION · LEAD MANAGEMENT · OPERATIONS · CONSULTING

THE BUSINESS PROBLEM

The organization had a public website, a CRM, training registration records, and an online store. Each held useful information, but the records were not consistently defined or connected. Inquiries could lose campaign context, product prices needed extra handling, and registration history was difficult to follow across people and companies.

MY APPROACH

I began with the data model, not the automation. I mapped record ownership, normalized field values, and clarified which identifiers and relationships each system should use. With that foundation in place, I built the integrations and follow-up workflows around the way staff actually worked.

01 / CUSTOMER DATA

Reliable lead records

Standardized form choices, inquiry types, and campaign parameters before passing them to Salesforce.

02 / RELATIONSHIPS

Connected record history

Mapped Accounts, Contacts, scheduled courses, registrants, host sites, and locations.

03 / COMMERCE

Consistent product details

Separated member and standard pricing while retaining categories, shipping fields, and virtual status.

04 / BUSINESS CONTEXT

Useful information at intake

Preserved source and intent so lead owners had context for routing, follow-up, and future reporting.

From clean records to working processes

Once the data was consistent, I connected the systems so staff could act on it without repeating the same work in multiple places.

01 / LEADS

Capture, route, follow up

Website inquiries entered Salesforce with the reason for contact and campaign context. A record-triggered Flow assigned the owner, notified staff, and created a follow-up Task.

02 / ECOMMERCE

Keep pricing aligned

Zapier retrieved Salesforce products and separate price-book entries, then sent structured data to a custom WordPress REST endpoint for WooCommerce updates.

03 / REGISTRATIONS

Preserve the relationships

Course and attendee records retained links between students, companies, scheduled sessions, and locations so participation could be viewed in context.

04 / CONSULTING

Track ongoing client work

I extended lead routing into an Account-based consultation model with engagements, contacts, and follow-up Tasks. This extension was built in Salesforce sandbox.

WHAT THE WORK MADE POSSIBLE

Staff had clearer inquiry ownership and source information. The storefront had a defined path for receiving product and pricing changes. Training records could support participant and company-level reporting, and consulting work had a structured place beyond the initial lead.

WHAT I WOULD DO SOONER

Agree on shared field definitions and matching keys before building the first integration. Those details had more impact on reliability than the automation triggers themselves.

Public version: Names, credentials, URLs, record IDs, and internal values have been removed or generalized. The consultation extension is a sandbox implementation; this brief does not claim a measured revenue increase.
